Introduction to Named Entity Recognition (NER)

- **Definition:** Named Entity Recognition (**NER**) is an information extraction task [atgoyalRecentNamedEntity2018] in Natural Language Processing (**NLP**) for identifying **entities** like names of **people**, **locations**, **organizations**, **dates**, and numerical expressions within text.

- **Early Contributions:** Lisa Rau's [-@rau1991extracting] work on extracting company names was pioneering, addressing the challenges posed by unknown words in NLP tasks.

Historical overview of NER

- **Origins:** The term “Named Entity” was formally introduced in the Sixth Message Understanding Conference (MUC-6), where it was recognized as essential for **extracting structured information**, such as names and temporal expressions [[@grishman1996message](#)].
- **Evolution:** Over time, methods evolved from rule-based approaches to **machine learning** and, eventually, to **deep learning**-based models [[@nadeau2007survey](#); [@liu2022overview](#)].
